

→ In java script we have 2 type of code

- ① Synchronous ← Pure js code
- ② Asynchronous

↳ Promises
callbacks
setTimeout
setInterval
Sync await

Now → JS is single threaded.

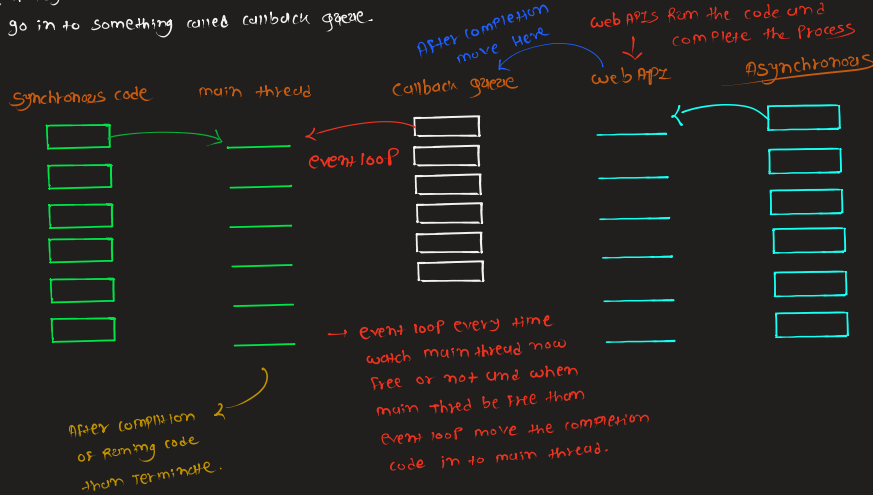

JS at a time only one operation should perform.

Ex: octa core processor

↳ JS at a time 1 core use.

→ In our code Synchronous code run firstly, this Synchronous code run java script's main thread because java script is an single threaded that's why on main threaded firstly Synchronous code run After that time Asynchronous code will run.

→ Synchronous code will run firstly and at that time if Asynchronous code present then this code go in to something called callback queue.

→ At that time Synchronous code is run if Asynchronous code come before that time then Asynchronous code go in to web API.

① main thread :- Firstly synch code run mean which code come in to main stack that code run.

② web API :- Browser provided many features and this features we can use in java script language. But in Actual these feature not provides provided java script language.
